

Gum Disease and the Cell Danger Response in Alzheimer's Disease

Gingivitis - the bacteria responsible for gingivitis and periodontal disease - are toxic to brain tissues. An abundance of this bacteria can generate toxic enzymes (gingipains), which can reach the brain and trigger dementia symptoms.

In a healthy brain

Gingipain toxins reach the brain -> Brain begins cell danger response and deploys amyloid peptides as a sticky “net” to trap and neutralize the toxins -> brain microglia (the immune system’s janitor cells) digest the amyloid-trapped debris -> Debris are flushed out via brain fluid during deep sleep - > The brain returns to normal operations

In a low energy brain

Gingipain toxins reach the brain -> Brain begins cell danger response and deploys amyloid proteins as a sticky “net” to trap and neutralize the toxins -> because the brain lacks energy, brain microglia (janitor cells) are too sluggish to digest the debris - > the trapped toxins and amyloid remain stagnant and build up in the brain, clumping together into plaques -> cell danger response remains stuck in chronic loop

The bottom line

Gum disease can be a trigger for Alzheimer’s disease in a low-energy brain. Maintaining an oral hygiene routine focused on raising the pH of the mouth (more

alkaline) and breaking up plaque (biofilm) significantly reduces the toxic burden on the brain, which can prevent the worsening of cognitive decline. By keeping your mouth healthy, you can prevent the worsening of cognitive decline and give the brain a break from toxins, freeing up its resources for rest, repair, and daily activity.
